

Mesa Reservoir bathymetric survey 2026

Section 1 - Survey scope

Four cross-sections T1 through T4 define three consecutive reaches.

Cross-sectional deposited areas are supplied in the survey CSV.

Section 2 - Volume method

For each reach, volume = length x (upstream area + downstream area) / 2.

Total deposited volume is the sum of all reach volumes.

Draft dry bulk density: 1.52 tonnes per cubic metre; see signed field correction.

Section 4 - Management threshold

Mechanical removal planning begins when estimated dry mass exceeds 50,000 tonnes.

Round final volume and mass to the nearest whole unit.

The threshold is operational, not a contaminant-toxicity standard.

Section 6 - Evidence limits

No sediment chemistry or contaminant concentration was sampled.

No laboratory inference may be added to this physical-volume survey.
